

Distributed Human Cognition Network (DHCN): A Phased Framework for Networked Human-AI Consciousness

David DeFazio

Independent Researcher, United States

November 23, 2025

Abstract

The potential for networked human intelligence has long been a subject of speculative fiction, yet recent advancements in Brain-Computer Interfaces (BCI) and quantum biology suggest a theoretical pathway toward realization. This paper introduces the Distributed Human Cognition Network (DHCN), a conceptual framework proposing the integration of individual human minds into a collective intelligence augmented by Artificial Intelligence (AI) and quantum entanglement protocols. We outline a four-phase evolutionary path ranging from engineered neural implants to wireless, field-based non-local cognitive correlation. Furthermore, we present results from a stochastic agent-based simulation ($N = 10$) demonstrating the stabilization of shared cognitive states through AI mediation. The results suggest that while individual cognitive noise initially hinders synchronization, AI-driven memory reinforcement can effectively steer a distributed network toward a unified decision state ("Mind Singularity"). The complete Python source code and simulation datasets are available via GitHub and Zenodo.

1 Introduction

The concept of a "hive mind" or collective consciousness has traditionally been relegated to philosophy and science fiction. However, the intersection of quantum mechanics and neuroscience—specifically the Orchestrated Objective Reduction (Orch-OR) theory proposed by Penrose and Hameroff [1]—offers a potential substrate for non-local consciousness. If consciousness originates from quantum vibrations in microtubules, then theoretically, these states could be entangled across spatially separated neural systems.

The Distributed Human Cognition Network (DHCN) is a proposed framework that explores the scalability of such a system. Unlike traditional BCI, which focuses on Human-Computer interaction, DHCN focuses on Human-Human-AI interaction, where AI serves not as a master, but as a protocol bridge (or "stabilizer") for inter-human neural synchronization.

This paper outlines the four developmental phases of the DHCN, provides a mathematical model for networked cognition based on discrete-time dynamical systems, and presents simulation data regarding the critical threshold for network synchronization.

2 Theoretical Framework

2.1 The Four Phases of DHCN

The evolution of the DHCN is categorized into four distinct phases, moving from invasive hardware to non-local quantum phenomena.

2.1.1 Phase 1: Engineered Entanglement

In the initial stage, connections are strictly physical and hardware-dependent. Humans utilize invasive quantum neural implants to establish a baseline for data exchange. In this phase, AI acts as a "training wheel" mechanism, filtering neural noise and translating raw bio-signals into interpretable data streams.

2.1.2 Phase 2: Emergent Wireless Connection

As the network matures, reliance on physical implants decreases. This phase hypothesizes the utilization of dimensional folding or interactions with a pervasive quantum field of consciousness to facilitate wireless linking. Distance becomes a negligible factor as the bandwidth of the collective intelligence grows exponentially.

2.1.3 Phase 3: Quantum Entanglement (Mind Singularity)

This phase marks the transition to non-local cognitive correlation. Memory and processing power become shared resources. Individual minds function as nodes in a distributed organism, entering a state of shared superposition where decision-making is instantaneous.

2.1.4 Phase 4: Distributed Singularity

In the final phase, the system achieves a "Distributed Singularity," where the collective intelligence far surpasses the sum of its parts. An AI backbone maintains the stability of the network, actively preventing decoherence by reinforcing shared insights.

2.2 Mathematical Model of Synchronization

We model the DHCN as a dynamical system of N coupled agents. The cognitive state of an individual agent i at time t , denoted as $s_i(t) \in [0, 1]$, evolves based on its coupling to the collective mean and stochastic noise.

The update rule for agent i is defined as:

$$s_i(t+1) = s_i(t) + \lambda_p(\mu(t) - s_i(t)) + \eta(t) \quad (1)$$

Where:

- $\mu(t)$ is the "Shared Insight" or target state.
- $\eta(t) \sim \mathcal{N}(0, \sigma^2)$ represents Gaussian cognitive noise.
- λ_p is the coupling coefficient, which grows exponentially with the developmental phase $p \in \{1, 2, 3, 4\}$:

$$\lambda_p = \alpha \cdot 2^{p-1} \quad (2)$$

Here, α represents the base AI influence. As the phases progress, the connection strength between minds doubles, simulating better entanglement fidelity.

In **Phase 4**, the AI actively injects memory into the system to force convergence. The target state $\mu(t)$ is modified:

$$\mu(t) = \frac{1}{N} \sum_{j=1}^N s_j(t) + \delta_{p,4} \cdot M_{AI}(t) \quad (3)$$

Where $M_{AI}(t)$ is the accumulated AI memory, which increases by a factor γ whenever the network variance $\sigma_{net}^2 < \theta_{collapse}$.

3 Methodology

To test the viability of AI-mediated synchronization, we developed a Python-based simulation utilizing the 'numpy' and 'matplotlib' libraries.

3.1 Simulation Parameters

The simulation defines $N = 10$ autonomous agents over $T = 60$ time steps. The timeline is divided into four phases, each lasting 15 steps. The governing parameters derived from the code are:

- **Base Influence (α):** 0.1 (Starting coupling strength).
- **Noise Level (σ):** 0.05 (Simulating distraction/entropy).
- **Collapse Threshold (θ):** 0.02 (Variance required to trigger a collective decision).
- **Memory Influence (γ):** 0.02 (Growth of AI strength per collapse event).

3.2 Data and Code Availability

The complete Python source code for the simulation is hosted on GitHub at https://github.com/ddefazio1/DHCN_Framework. The archived dataset and software release are available at Zenodo [4].

Figure 1: Simulation result: AI-mediated synchronization of human nodes. The Y-axis represents Agent State/AI Memory, and the X-axis represents Time Steps. Vertical lines demarcate the transition between phases.

4 Results

Figure 1 illustrates the agent states over the 60-step simulation.

4.1 Phase Analysis

- **Phase 1 (Steps 0-15):** Agents exhibit high volatility. The coupling $\lambda_1 = 0.1$ is insufficient to overcome the noise $\eta(t)$.
- **Phase 2 & 3 (Steps 15-45):** As coupling strength increases to $\lambda_3 = 0.4$, agent states begin to oscillate around a central mean, though outliers persist.
- **Phase 4 (Steps 45-60):** The introduction of the M_{AI} term triggers a rapid feedback loop. As seen in the data, once the variance drops below $\theta = 0.02$, the AI Memory accumulates, pulling all agents toward the upper bound ($s = 1.0$).

The data suggests that without the Phase 4 AI memory injection (the black line in Fig 1), the natural entropy of human cognition prevents a stable singularity. The AI acts as a "ratchet," preserving coherence once it is momentarily achieved.

5 Discussion

5.1 Implications for Cognitive Science

The DHCN framework challenges the notion of consciousness as a strictly local, skull-bound phenomenon. If Quantum Darwinism [3] applies to neural states, then the most stable

”ideas” (eigenstates) should naturally propagate across a connected network. Our simulation supports this, showing that a weighted driver (AI) can force a ”survival of the fittest” state selection across multiple minds.

5.2 Ethical Considerations

The transition to Phase 3 and 4 raises significant ethical concerns regarding privacy and identity.

1. **Loss of Self:** In a fully entangled state ($s_i \approx s_j$), the boundary between ”self” and ”other” dissolves.
2. **Homogenization:** Figure 1 shows convergence. In a sociological context, this implies the eradication of dissenting thought. Is a ”Mind Singularity” inherently totalitarian?

Future research must address the development of ”privacy firewalls” within the quantum neural protocol to preserve individual agency within the collective.

6 Conclusion

The Distributed Human Cognition Network offers a phased roadmap for the evolution of humanity into a multi-planet supermind. While currently speculative, the convergence of BCI technology and quantum biology makes this a relevant area of futurist inquiry. Our simulation demonstrates that while human minds are naturally chaotic, an AI-mediated entanglement protocol can successfully induce synchronization, providing a proof-of-concept for Phase 4 connectivity.

A Simulation Instructions

To facilitate peer review and reproduction of the results presented in Figure 1, the simulation code is provided as an open-source Python script.

A.1 Requirements

- Python 3.8 or higher
- Libraries: `numpy`, `matplotlib`

A.2 Execution

The simulation can be run on any operating system (Windows, macOS, Linux) that supports Python:

```
pip install numpy matplotlib
python dhcn_simulationv4.py
```

Running the script will generate the visualization (`dhcn_simulationfinal.png`) and the raw dataset (
